How can we then obtain reliable information on low energy K(n)N interaction?

Key observables:
Shift (ϵ), Width (Γ)
and X-ray Yield

First Preface

“ The most *important experiment* to be carried out in low energy *K*-meson physics today is the *definitive* determination of the energy level shifts in the K^-p and K^-d atoms, because of their direct connection with the physics of $\bar{K}N$ interaction and their complete independence from all other kinds of measurements which bear on this interaction”.

R.H.Dalitz

Proc. Int. Conf. on “Hypernuclear and Kaon Physics”,
Heidelberg 1982.

The combined use of Kaon Trigger and SDDs drift time allows to reduce the asynchronous background by a factor $\sim 2 \cdot 10^4$

Kaonic atoms measurements @ DAΦNE

The trigger is generated by the coincidence of 2 back-to-back scintillators
The ToF is different ($\sim 2 \text{ ns}$) for Kaons, $m(K) \sim 500 \text{ MeV}/c^2$ and light particles originating from beam-beam and beam-environment interaction (MIPs).
Can efficiently discriminate by ToF Kaons and MIPs!

The VETO-1 system for signal identification

Silicon Drift Detectors for
HADronic Atom
Research by
Timing Application

SIDDHARTA-2 is equipped with a VETO system that measure the arrival time of charged particles produced after the K^- absorption.

It can be used to asses if a K^- is stopped in a solid or gaseous target

Proposal(s) for future measurements @ DAΦNE

Silicon Drift Detectors for
HADronic Atom
Research by
Timing Application

Proposal for future extensive kaonic atoms measurements @ DAFNE to be performed exploiting:

- 450 mm SDD (light KA, up to 15 keV)
- 1-2 mm SDD (light KA, up to 40 keV)
- CdZnTe detectors (Intermediate mass KA)
- HPGe detectors (Heavy KA)
- Crystal Spectrometer (High-Res light KA)

Kaonic atoms at DAΦNE collider: a strangeness adventure
C. Curceanu et al., doi.org/10.3389/fphy.2023.1240250

SDD 1mm

Cd(Zn)Te

HPGe

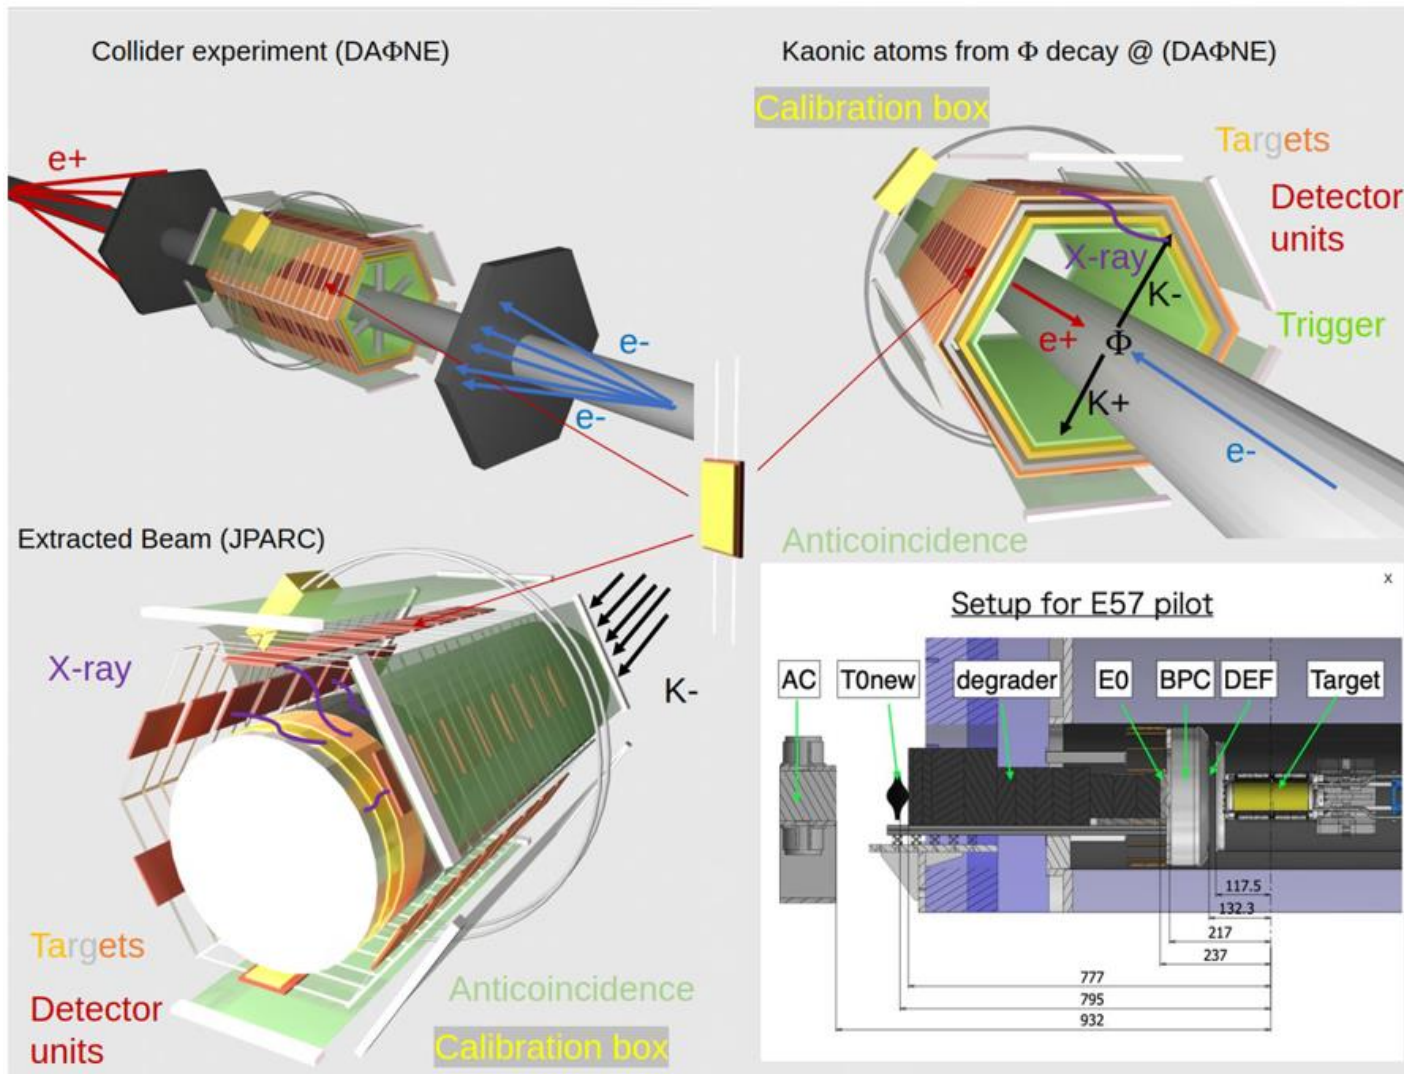

Extensive Kaonic Atoms research: from Lithium and Beryllium to Uranium

Proposal(s) for future measurements @ DAΦNE

Silicon Drift Detectors for HAAdronic Atom Research by Timing Application

At J-PARC, the 10^{7-8} K^-/s stopping in the target/degrader will ensure a statistic of orders of magnitude higher than that collectable at DAFNE.

What is lost for D_2 is gained for solid targets measurements

Enhanced probability to systematically study Σ^- atoms

Conclusions

DAΦNE is a unique facility in the world to investigate low energy strangeness nuclear physics, and the possibility to perform such important measurements at DAΦNE (and J-PARC) should not be missed

To Carlo & Hannes

We dedicate all our efforts and results to Prof. Carlo Guaraldo and Prof. Johann Zmeskal, who conceived, designed, realized and led the DEAR, SIDDHARTA and SIDDHARTA-2 experiments, and without whom none of these results would have never been achieved.

October, 2012

To Carlo & Hannes

We dedicate all our efforts and results to Prof. Carlo Guaraldo and Prof. Johann Zmeskal, who conceived, designed, realized and led the DEAR, SIDDHARTA and SIDDHARTA-2 experiments, and without whom none of these results would have never been achieved.

October, 2012

My special thanks also to prof. Yamazaki for the nice and fruitful discussions during my Ph.D and PostDoc

Thanks for your attention

KH and Kd

Theoretical predictions for the kaonic deuterium $1s$ level shift and width

The low X-rays yield has, until now, prevented the observation of $1s$ level transitions in kaonic deuterium.

Antikaon-deuteron scattering length

$$\epsilon_{1s} + \frac{i}{2}\Gamma_{1s} = 2\alpha^3\mu^2 a_{K-d} / [1 + 2\alpha\mu(\ln\alpha - 1)a_{K-d}]$$

New measurements of Kaonic Helium not confirming the old ones

Many of the available data on “lower levels” have big uncertainties

Some widths are actually UNmeasured

Many of them are hardly compatible among each other (Sulfur “puzzle”)

Relative yields with upper levels are not always measured

Absolute yields are basically unknown (except for few transitions)

New measurements (with improved precisions) are important to be performed

The K^- mass problem

Large uncertainty \rightarrow 26 p.p.m,
 compared to charged pion:
 $m_\pi = 139.57061 \pm 0.00023$ MeV, 1.6 p.p.m

The K^- mass problem

Large uncertainty \rightarrow 26 p.p.m,
compared to charged pion:
 $m_\pi = 139.57061 \pm 0.00023$ MeV, 1.6 p.p.m

Precise QED investigations with KNe

High- n transition in kaonic atoms represents an ideal test bench for BSQED:

1. For high- n transitions, the strong interaction contribution is negligible
2. Due to the compactness of the kaonic atom the QED effects such as vacuum polarization are enhanced compared to high- Z ions
3. BSQED corrections for kaonic neon are of the order of tens of eV for first-order QED effects and order of 0.2 eV for second-order QED effects

Kaonic neon energy transitions and absolute yields at the density of 3.60 ± 0.18 g/l. The first error is statistical, the second systematic.

Transition	Energy [eV]	Yield
K-Ne (10 → 8)	$7191.21 \pm 4.91 \pm 2.00$	$0.010 \pm 0.001 \pm 0.001$
